

## Part O — Reflection (~200 words)

The easiest part of converting the paper was the mechanical text-to-LaTeX transfer — moving prose, section headings, and `natbib` citations across preserved almost perfectly whenever Prism’s chat was working. The most manual effort went into two places the lab doesn’t obviously flag: building `references.bib` correctly without inventing missing DOIs or page numbers, and — more unexpectedly — verifying that AI-inserted paragraphs hadn’t quietly dropped structural elements. Prism’s chat compiled a document that “looked” complete but had silently lost 22 of 24 in-text `Section~\ref{}` cross-references during paraphrasing; nothing in the compiler flagged this, since the document was still valid LaTeX. Catching it required deliberately counting `\ref{}` occurrences against the source rather than trusting a successful compile.

The most useful Prism feature was the direct Monaco code editor, which stayed reliable even when the AI chat suffered a sustained sandbox-provisioning outage (7 consecutive failures, documented in the Error Log). The project did compile in Overleaf without any modification, which is reassuring, but it doesn’t mean AI-assisted output needs no supervision — it means the LaTeX was syntactically sound, not that its content was automatically correct. The key precaution: never accept an AI edit on the strength of “it compiled.” Compilation success and scientific/structural fidelity are different questions, and only the second one is the researcher’s responsibility to verify.
